

# Intro to R

## Part 3: Visualization

Prof. Bisbee

Vanderbilt University

Lecture Date: 2023/01/23

Slides Updated: 2023-01-18

# Agenda

## 1. Recap of last lecture

- Using packages: `install.packages()` & `require()`
- Loading and manipulating data: `readRDS()` and `%>%`

## 2. Plotting in R

- `ggplot` (+ instead of `%>%`)

# Loading Packages & Data

- Create an `.Rmd` file and save to your `code` folder
  - Accept defaults, Save As... (with a good name), then `knit`
- Load the `tidyverse` package

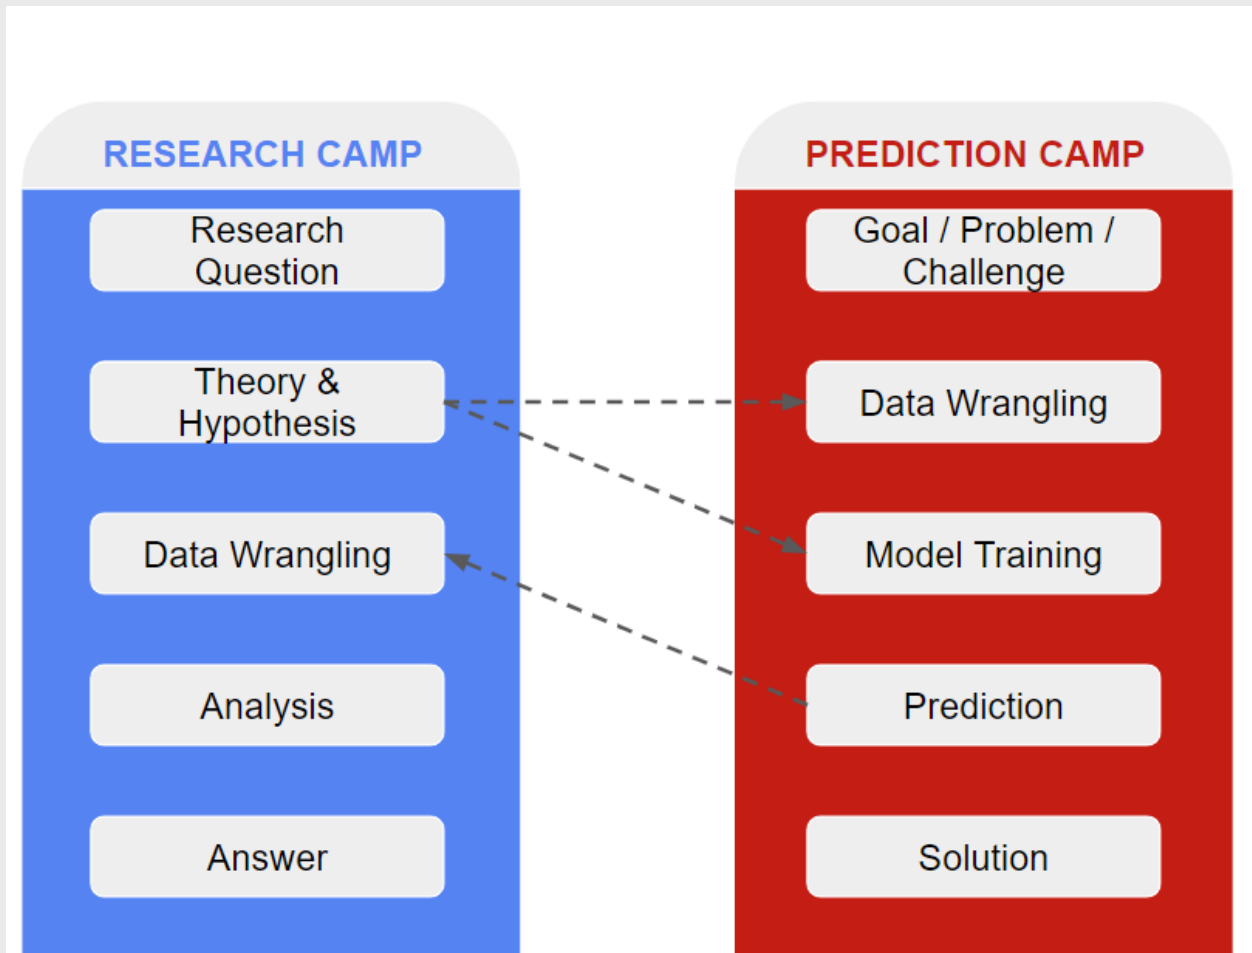

```
require(tidyverse)
```

- Download `sc_debt.Rds` from [GitHub](#) and save to your `./data` folder
- Now load the data with `readRDS("[PATH TO DATA]/sc_debt.Rds")`
  - We **create** an "object" to store the data using a left-arrow: `<-`

```
df <- readRDS("../data/sc_debt.Rds")
```

- NB: `../` means "go up one folder"

# The Two Camps

# The Research Camp

- RQ: How might admissions and SAT scores be **related**?
  - Theory: selective schools have stricter criteria
  - Hypothesis: admissions and SAT scores should be **negatively** related
- How can we test this hypothesis?

# Previously: `summarise()`

- We can combine base R functions with `tidyverse` functions!
  - Base R: `mean()`
  - `tidyverse`: `summarise()` (aka `summarize()`)
- Overall average SAT scores

```
df %>%  
  summarise(mean_sat = mean(sat_avg, na.rm=T))
```

```
## # A tibble: 1 × 1  
##   mean_sat  
##   <dbl>  
## 1    1141.
```

# Previously: `summarise()`

- Let's unpack this

```
df %>%  
  summarise(mean_sat = mean(sat_avg, na.rm=T))
```

- Create new variable `mean_sat` that contains the `mean()` of every school's average SAT score
- `na.rm=T` means we want to ignore missing data. If not?

```
df %>%  
  summarise(mean_sat = mean(sat_avg))
```

```
## # A tibble: 1 × 1  
##   mean_sat  
##   <dbl>  
## 1      NA
```

# summarise() + filter()

- Recall we want see if more selective schools have higher SAT scores

```
df %>%  
  filter(adm_rate < .1) %>%  
  summarise(mean_sat_LT10 = mean(sat_avg, na.rm=T))
```

```
## # A tibble: 1 × 1  
##   mean_sat_LT10  
##           <dbl>  
## 1          1510.
```

```
df %>%  
  filter(adm_rate > .1 & adm_rate < .2) %>%  
  summarise(mean_sat_1020 = mean(sat_avg, na.rm=T))
```

```
## # A tibble: 1 × 1  
##   mean_sat_1020  
##           <dbl>  
## 1          1424.
```

# summarise() + group\_by()

- One final `tidyverse` function: `group_by()`

```
df %>%  
  group_by(selective) %>%  
  summarise(mean_sat = mean(sat_avg, na.rm=T))
```

```
## # A tibble: 3 × 2  
##   selective mean_sat  
##   <dbl>     <dbl>  
## 1      0     1135.  
## 2      1     1510.  
## 3     NA      NaN
```

# Plotting data

- Let's plot the data instead of writing many of these `summarise()` functions
- Visualization in R uses `ggplot()` function
  - Inputs: `aes(x,y,...)` (elipses `...` indicates many more inputs)
  - `x` is the x-axis (horizontal)
  - `y` is the y-axis (vertical)

# ggplot()

- Attach `ggplot()` to your data with `%>%`

```
df %>%  
  ggplot()
```

# ggplot()

- Then tell it what to put in the x-axis and y-axis
- What should go on these axes?
- **Theory**: Selective schools choose higher scoring students
  - Selective schools **explain** higher scores
  - Selective schools: **independent variable** / **explanatory variable** / **predictor** /  $X$
  - Higher scores: **dependent variable** / **outcome variable** /  $Y$
- Selective schools go on the x-axis, SAT scores go on the y-axis

# ggplot()

```
df %>%  
  ggplot(aes(x = adm_rate, y = sat_avg))
```

# ggplot()

- This gives us an empty plot
- We have the correct variables on the correct axes...
- ...but we need to choose how to display them
- There are many different `ggplot()` functions to choose from
  - `geom_point()` creates one point for each x and y coordinate
  - `geom_bar()` creates a barplot
  - `geom_histogram()` creates a histogram
  - `geom_density()` creates a density plot
  - `geom_boxplot()` creates a box-and-whisker plot

# ggplot()

- We **add** a second `ggplot()` function to the first with a plus sign +
  - **NB:** This is JUST LIKE THE PIPE OPERATOR `%>%` in `tidyverse`!
- Since `adm_rate` (the x-axis variable) and `sat_avg` (the y-axis variable) are both numeric ("continuous") measures, we will use `geom_point()`
  - We will come back to **variable types** and how to visualize them later

# ggplot()

```
df %>%  
  ggplot(aes(x = adm_rate, y = sat_avg)) +  
  geom_point()
```

# Plotting data

- Let's unpack this
  - `aes(x,y)` sets the basic aesthetics for the plot
  - `geom_point()` tells `ggplot()` how to visualize those aesthetics
  - These two parts are linked with the `+`. Similar to...?
  - ...the `%>%` in `tidyverse`!
  - We can force aesthetics by setting code outside the `aes()`

```
df %>%  
  ggplot(aes(x = adm_rate_pct, y = sat_avg)) +  
  geom_point(color = 'red')
```

# Plotting data

# Plotting data

- Or we can make more aesthetics dependent on the data

```
df %>%  
  ggplot(aes(x = adm_rate, y = sat_avg,  
             color = stabbr)) +  
  geom_point()
```

# Plotting data

# Interpreting the plot

- We **hypothesized** that admissions and SAT scores are negatively related
  - Is this supported in the data?
- Let's add a line of best fit with `geom_smooth()`

```
df %>%  
  ggplot(aes(x = adm_rate, y = sat_avg)) +  
  geom_point() +  
  geom_smooth(method = 'lm', se = F)
```

# Plotting data

- Which school is most selective but also with the lowest SAT?
  - This is an **outlier**
  - This school is the **furthest** from our [theory](#)

```
df %>%  
  mutate(out = ifelse(adm_rate < .25 & sat_avg < 1000,  
                      instnm, # Value if TRUE  
                      NA)) %>% # Value if FALSE  
  filter(!is.na(out)) %>%  
  select(instnm, adm_rate, sat_avg)
```

```
## # A tibble: 1 × 3  
##   instnm      adm_rate sat_avg  
##   <chr>      <dbl>   <int>  
## 1 Dallas Christian College 0.130     917
```

# Plotting data

- We can add this as a label!

```
df %>%  
  mutate(out = ifelse(adm_rate < .25 & sat_avg < 1000,  
                      instnm,  
                      NA)) %>%  
  ggplot(aes(x = adm_rate, y = sat_avg,  
            label = out)) +  
  geom_point() +  
  geom_text()
```

# Plotting data

# Plotting data

- Let's accentuate the outlier more with color

```
df %>%  
  mutate(out = ifelse(adm_rate < .25 & sat_avg < 1000,  
                      instnm,  
                      NA)) %>%  
  ggplot(aes(x = adm_rate, y = sat_avg,  
            color = out, label = out)) +  
  geom_point() +  
  scale_color_manual(name = "Outlier", values = c('red', 'black')) +  
  geom_text(hjust = 0, vjust = 1, color = 'black', size = 3)
```

# Plotting data

# Categorical Data

- Thus far, we have used two continuous variables: `adm_rate` and `sat_avg`
  - We used `geom_point()` to display the data as a scatterplot
- What if we wanted to determine which state is home to the most selective schools?
- Use `group_by()` and `summarise()`

```
df %>%  
  group_by(stabbr) %>%  
  summarise(selective_avg = mean(adm_rate, na.rm=T))
```

```
## # A tibble: 51 × 2  
##   stabbr selective_avg  
##   <chr>         <dbl>  
## 1 AK           0.827  
## 2 AL           0.654  
## 3 AR           0.676  
## 4 AZ           0.843  
## 5 CA           0.592  
## 6 CO           0.768
```

# Categorical Data

- This gives us two variables again, but one of them is now a **character** type
- Can we plot this as a scatterplot?

```
p <- df %>%  
  group_by(stabbr) %>%  
  summarise(selective_avg = mean(adm_rate,na.rm=T)) %>%  
  ggplot(aes(x = stabbr,y = selective_avg)) +  
  geom_point()
```

# Categorical Data

- Yes...but it isn't very pretty

p

# Categorical Data

- Let's try a barplot instead using `geom_bar()`
  - NB: `geom_bar()` will automatically try to count the values on the x-axis

```
df %>%  
  ggplot(aes(x = stabbr)) +  
  geom_bar()
```

# Categorical Data

- This is fine if we just want to know which states have the most schools in our data
- But we want to put the average admissions rate on the y-axis instead
  - Need to **override** `geom_bar()` default behavior

```
p <- df %>%  
  group_by(stabbr) %>%  
  summarise(selective_avg = mean(adm_rate, na.rm=T)) %>%  
  ggplot(aes(x = stabbr, y = selective_avg)) +  
  geom_bar(stat = 'identity')
```

# Categorical Data

p

# Categorical Data

- Getting a little better, but still ugly
- Use `reorder()` to sort the x-axis values by the y-axis

```
p <- df %>%  
  group_by(stabbr) %>%  
  summarise(selective_avg = mean(adm_rate, na.rm=T)) %>%  
  ggplot(aes(x = reorder(stabbr, selective_avg), y = selective_avg)) +  
  geom_bar(stat = 'identity')
```

# Categorical Data

- Even better!

p

# Plot Tweaking

- We could go even further and swap the x and y-axes (although this isn't always a good idea!)

```
p <- df %>%  
  group_by(stabbr) %>%  
  summarise(selective_avg = mean(adm_rate,na.rm=T)) %>%  
  ggplot(aes(y = reorder(stabbr,selective_avg),x = selective_avg)) +  
  geom_bar(stat = 'identity')
```

# Plot Tweaking

p

- Still ugly though! We want to tweak the labels with `labs()`

# Plot Tweaking

```
p +  
  labs(title = "Average Admissions by State",  
        x = "Admissions Rate",  
        y = "State")
```

# Conclusion

- What to take away
  1. Which variables go on which axes
  2. How to put these on a `ggplot()` figure
  3. How to create a visualization of these variables
- This wraps up the crash course in R
  - **REMEMBER:** This class is *inherently* challenging because of R
  - The course is graded leniently to reflect the inherent difficulty of the material

# Quiz & Homework

- Go to Brightspace and take the fourth quiz
  - The password to take the quiz is ####
- **Homework:**
  1. Work through Intro\_to\_R\_Part3\_hw.Rmd
  2. Complete Problem Set 1
